# Deracemization Concepts

- Deracemization is inherently endothermic due to the decrease in entropy required:

# Deracemization Concepts

- Deracemization is inherently endothermic due to the decrease in entropy required:

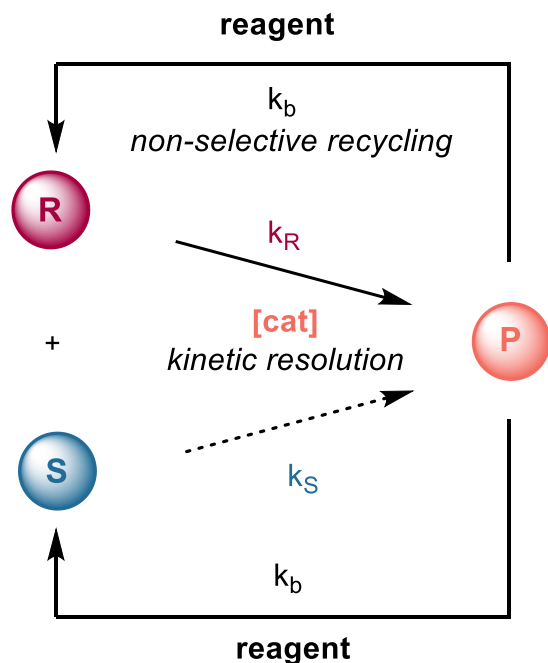

- Early strategies used a KR cycling process with an external reagent to drive the cycle:

# Deracemization Concepts

- Deracemization is inherently endothermic due to the decrease in entropy required:

- Early strategies used a KR cycling process with an external reagent to drive the cycle:

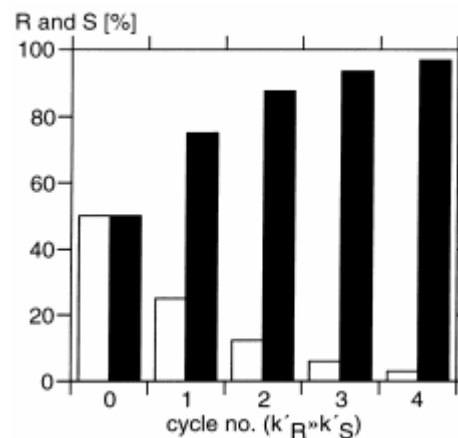

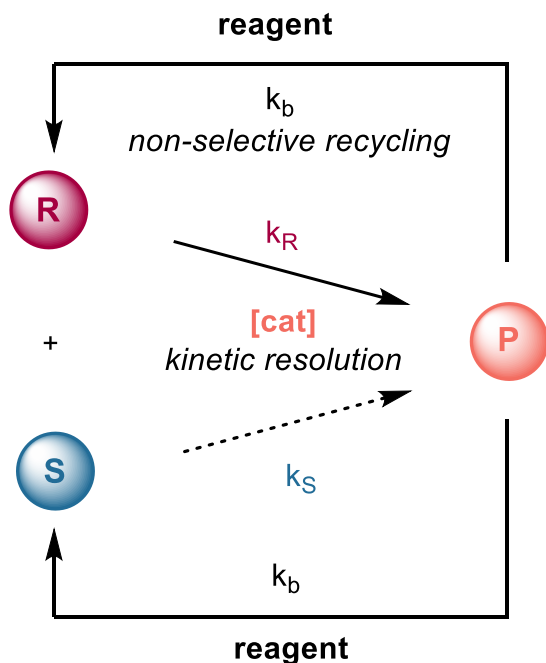

# Deracemization Concepts

- Deracemization is inherently endothermic due to the decrease in entropy required:

- Early strategies used a KR cycling process with an external reagent to drive the cycle:

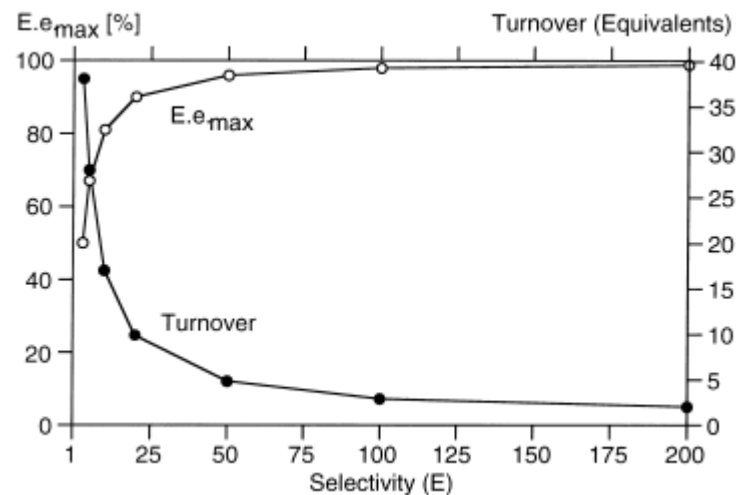

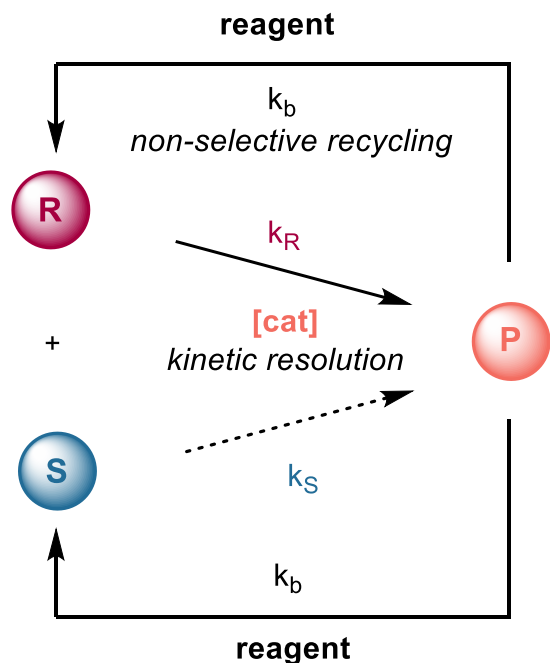

Repeated cycling leads to the accumulation of (S)

# Deracemization Concepts

- Deracemization is inherently endothermic due to the decrease in entropy required:

- Early strategies used a KR cycling process with an external reagent to drive the cycle:

**Selectivity Factor  $E = k_R/k_S$**

# Deracemization Concepts: Application of Substrate Cycling

- Deracemization is inherently endothermic due to the decrease in entropy required:

# Deracemization Concepts: Application of Substrate Cycling

- Deracemization is inherently endothermic due to the decrease in entropy required:

- Early examples typically used the oxidation/reduction cycling of alcohols or amines:

# Deracemization Concepts: Application of Substrate Cycling

- Deracemization is inherently endothermic due to the decrease in entropy required:

- Early examples typically used the oxidation/reduction cycling of alcohols or amines:

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

- The concept of substrate cycling has prompted numerous proposals using closed systems:

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

- The concept of substrate cycling has prompted numerous proposals using closed systems:

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

- The concept of substrate cycling has prompted numerous proposals using closed systems:

Experimental tests inevitably result in racemic mixtures

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

- The concept of substrate cycling has prompted numerous proposals using closed systems:

Experimental tests inevitably result in racemic mixtures

- The positive  $\Delta G$  of deracemization immediately shows these ideas are impossible
- Yet these proposals remained common

## Deracemization: A Common Pitfall

- Deracemization is inherently endothermic due to the decrease in entropy required:

- The concept of substrate cycling has prompted numerous proposals using closed systems:

Experimental tests inevitably result in racemic mixtures

- The positive  $\Delta G$  of deracemization immediately shows these ideas are impossible
- Yet these proposals remained common
- To understand why such proposals are infeasible, the **principle of microscopic reversibility** must be considered

# *Deracemization: The Principle of Microscopic Reversibility*

- The principle of microscopic reversibility states:

## *Deracemization: The Principle of Microscopic Reversibility*

- The principle of microscopic reversibility states:
  - At equilibrium, any molecular process and the reverse of that process occur at the same rate

## *Deracemization: The Principle of Microscopic Reversibility*

- The principle of microscopic reversibility states:
  - At equilibrium, any molecular process and the reverse of that process occur at the same rate
  - Accordingly, the reaction path in the reverse must be the reverse of the forward reaction

# *Deracemization: The Principle of Microscopic Reversibility*

- The principle of microscopic reversibility states:
  - At equilibrium, any molecular process and the reverse of that process occur at the same rate
  - Accordingly, the reaction path in the reverse must be the reverse of the forward reaction
- Thus the reverse reaction of a catalytic step must proceed via the catalytic path:

# Deracemization: The Principle of Microscopic Reversibility

- The principle of microscopic reversibility states:
  - At equilibrium, any molecular process and the reverse of that process occur at the same rate
  - Accordingly, the reaction path in the reverse must be the reverse of the forward reaction
- Thus the reverse reaction of a catalytic step must proceed via the catalytic path:

The lowest path backward must always be identical to the lowest path forward

## *Deracemization: Applying the Principle of Microscopic Reversibility*

- When considered from this perspective, the issue with closed system recycling is clear:

# Deracemization: Applying the Principle of Microscopic Reversibility

- When considered from this perspective, the issue with closed system recycling is clear:

# Deracemization: Applying the Principle of Microscopic Reversibility

- When considered from this perspective, the issue with closed system recycling is clear:

# Deracemization: Applying the Principle of Microscopic Reversibility

- When considered from this perspective, the issue with closed system recycling is clear:

- “Attempts to recycle a catalytic reaction back by its uncatalyzed route clearly breaks the rules”

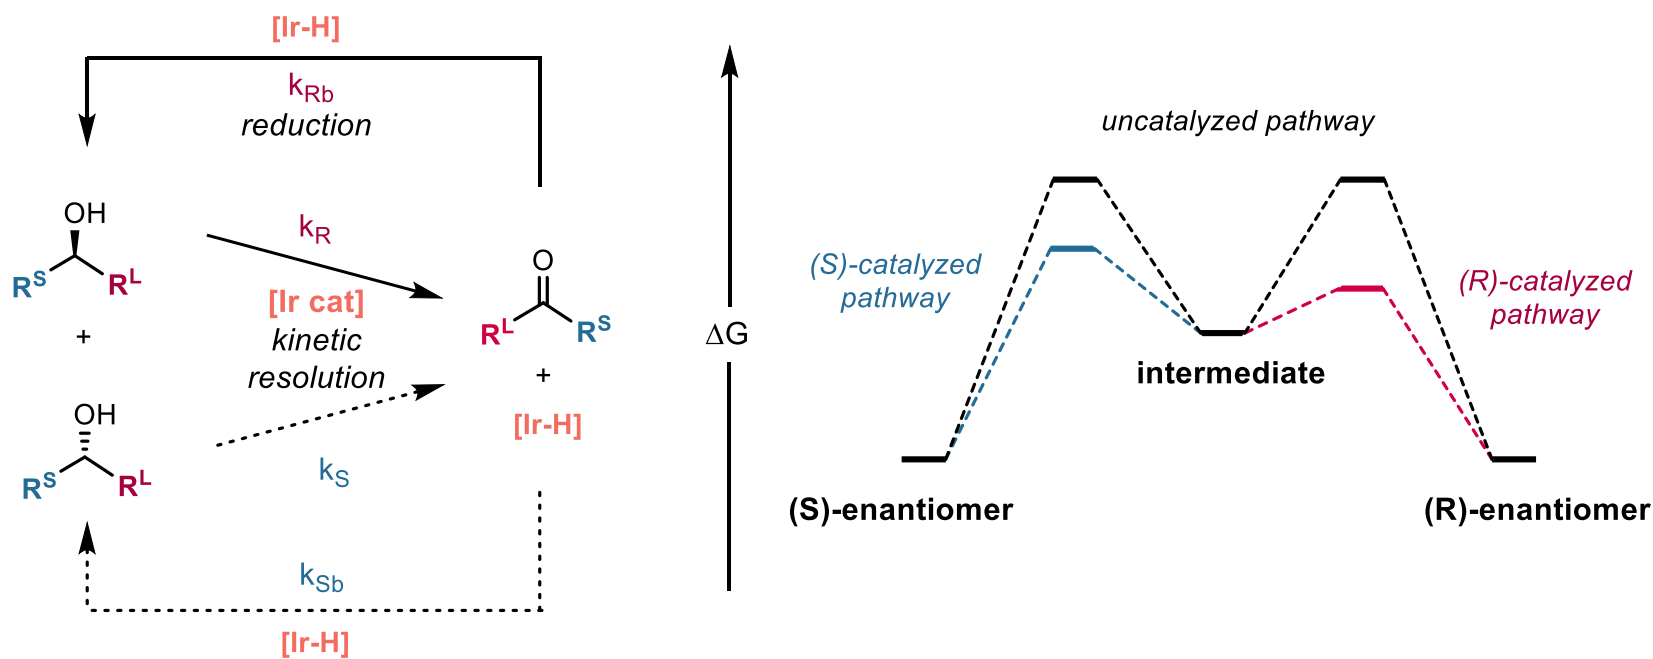

## *Deracemization: Applying the Principle of Microscopic Reversibility*

- When considered from this perspective, the issue with closed system recycling is clear:

# Deracemization: Applying the Principle of Microscopic Reversibility

- When considered from this perspective, the issue with closed system recycling is clear:

# Deracemization: Applying the Principle of Microscopic Reversibility

- When considered from this perspective, the issue with closed system recycling is clear:

- The energetics that favor the catalytic conversion of the undesired (R)-enantiomer also will favor its re-formation from the intermediate (if  $k_R$  is large, then  $k_{Rb}$  must also be)
- The closed system will inexorably proceed towards equilibrium (racemization)

# Deracemization: Overcoming the Limitations of Closed Systems

- To overcome the limitation of a closed systems, a source of chemical or light energy is needed

# Deracemization: Overcoming the Limitations of Closed Systems

- To overcome the limitation of a closed systems, a source of chemical or light energy is needed

- The principle of microscopic reversibility prohibits a single catalytic step from deracemizing a reaction
- Two or more steps proceeding through distinct mechanisms are necessary

# Deracemization: Overcoming the Limitations of Closed Systems

- To overcome the limitation of a closed systems, a source of chemical or light energy is needed

- The principle of microscopic reversibility prohibits a single catalytic step from deracemizing a reaction
- Two or more steps proceeding through distinct mechanisms are necessary
  - Chemical compatibility of reagents can be a challenge, especially in redox cycling
  - Temporal separation is one possible solution (stepwise reactions)
  - Photochemical methods would be ideal, but few candidate systems exist

## *Deracemization: Phase Separation and Chemical Energy*

- Catalytic enantioselective reduction of imines with chiral phosphoric acids is well known:

# Deracemization: Phase Separation and Chemical Energy

- Catalytic enantioselective reduction of imines with chiral phosphoric acids is well known:

# Deracemization: Phase Separation and Chemical Energy

- Catalytic enantioselective reduction of imines with chiral phosphoric acids is well known:

- The Toste group found CPAs can facilitate phase-transfer oxidation of indolines, with low selectivity

## *Deracemization: Phase Separation and Chemical Energy*

- This phase transfer system appeared suited for a deracemization strategy:

# Deracemization: Phase Separation and Chemical Energy

- This phase transfer system appeared suited for a deracemization strategy:

# Deracemization: Phase Separation and Chemical Energy

- This phase transfer system appeared suited for a deracemization strategy:

- However, no deuterium erosion (no reaction) was observed when the two cycles were combined:

## Deracemization: Phase Separation and Chemical Energy

- While the two reagents were insoluble, they were consuming each other in the solid phase:

# Deracemization: Phase Separation and Chemical Energy

- While the two reagents were insoluble, they were consuming each other in the solid phase:

- Therefore, a three-phase strategy (solid, organic, and aqueous) was devised:

# Deracemization: Phase Separation and Chemical Energy

## Deracemization of Ureas: Stereoinversion

- This system was also capable of performing selective stereoinversion:

# Deracemization of Ureas: Stereoinversion

- This system was also capable of performing selective stereoinversion:

## *Conclusion*

- Deracemization has recently seen increased activity as a field of asymmetric catalysis

## *Conclusion*

- Deracemization has recently seen increased activity as a field of asymmetric catalysis
- Light is a particularly promising energy source to drive selective formation of a single enantiomer

# Conclusion

- Deracemization has recently seen increased activity as a field of asymmetric catalysis
- Light is a particularly promising energy source to drive selective formation of a single enantiomer

# Conclusion

- Deracemization has recently seen increased activity as a field of asymmetric catalysis
- Light is a particularly promising energy source to drive selective formation of a single enantiomer

## *Conclusion*

- Deracemization has recently seen increased activity as a field of asymmetric catalysis
- Light is a particularly promising energy source to drive selective formation of a single enantiomer
- Considerable limitations remain with regards to substrate scope and synthetic utility

## Conclusion

- Deracemization has recently seen increased activity as a field of asymmetric catalysis
- Light is a particularly promising energy source to drive selective formation of a single enantiomer
- Considerable limitations remain with regards to substrate scope and synthetic utility
- However, further study of system and catalyst design may result in more practical systems:
